

# 1 **RegRep Classification / Interfacing**

2 **Draft, Version 0.1, 13 September 2000**

3 Working Document.

4

---

## 5 **Abstract**

6 The need is to define both the classification system and the associated interface semantics  
7 for RegRep as XML structures and methods.

## 8 **Status**

9 *This draft represents the blending of current practical work in a variety of areas with*  
10 *XML, including the latest W3C Schema and Datatyping drafts, ISO11179, OASIS*  
11 *Registry and IETF WebDav DASL work.*

## 12 **Contributors**

## 55 2. Introduction

56 The objective of this document is to provide the necessary details for a understanding and  
57 specification details of the classification and interfacing to information stored in an  
58 ebXML compliant Registry/Repository.

59 The top level is the *classifications*. This mechanism allows you to group together industry  
60 vertical sets of transactions so you can quickly and easily find the particular business  
61 functional components that you require based on business use and context.

62

### 63 2.1 Design Goals

64 The ebXML principles require that the XML syntax used must be:

- 65 1) Simple to understand, to learn, read and use.
- 66 2) Provide a concise feature function set thereby ensuring consistent implementations,  
67 interoperability, and low cost of adoption. Each feature must earn its place based on  
68 widespread business need and applicability.
- 69 3) Separate the query, change and representation syntax, and use existing work such as  
70 IETF WebDav DASL wherever possible.
- 71 4) Support the storage and retrieval of ebXML Business Process and Core Component  
72 definition methods.
- 73 5) Provide a human interface for information discovery via a direct browser form based  
74 interactions and allowing rendering with multilingual support.
- 75 7) Provide a simple metaphor to migrate and express existing data dictionaries and  
76 related content such as COBOL copybooks, SQL table definitions, CICS structures,  
77 program data structures, business data dictionaries and similar information content  
78 quickly and easily into.
- 79 8) Be based on the W3C XML markup syntax, with minimal use of extended features,  
80 and be consistent with and interoperable with the ebXML technical specifications.
- 81 9) Above all, provide both large industry partners and small businesses with mission  
82 critical high volume, high performance, and open public standard based interchanges.  
83 Coupled with the long term means to conduct and maintain cost effective electronic  
84 information exchanges that can be simply deployed and exploited by as large a cross-  
85 section of the workforce as possible.

## 86 **2.2 Terminology and Concepts**

87 The following extracts are provided to aid understanding of this document.

### 88 **2.2.1 Classification**

89 A classification is a partition of a given collection of items into mutually exclusive and  
90 collectively exhaustive sub-collections. A classification depends upon a pre-existing  
91 specification of a hierarchy of values, names, and codes called a classification scheme.  
92 Registry items in a Registry may be classified by as many classification schemes as  
93 deemed appropriate by the Submitting Organization. A classification scheme can have  
94 an associated XML structure that defines the information within the classification. An  
95 example would be currency table that has currency code, currency symbol, name, country  
96 code, conversion rate and date associated with it. Classifications may be referential; so  
97 one classification may depend on another classification.

98  
99 A distinction can therefore be made between classifications that describe physical  
100 business content as above, and classifications that describe collections of like information  
101 within the registry itself, such as XML structure layouts associated with business  
102 processes.

### 103 **3.2.1 Coded Classification Scheme**

104 A coded classification scheme is a hierarchy of values that can be referenced by a  
105 classification. A coded classification scheme can vary from a simple set of values to a  
106 complex multi-level hierarchy. An example of a simple single-level coded classification  
107 is the set {Freshman, Sophomore, Junior, Senior} used to partition a collection of  
108 students. An example of a more complicated classification scheme is one based on the  
109 hierarchy of all living things with named levels for Kingdom, Phylum, Class, Order,  
110 Family, Genus and Species.

### 111 **4.2.1 Package**

112 A Package is a conceptual notion used to identify a set of registered objects. It is defined  
113 to be a registered object that is a set of pointers to other registered objects. Using this  
114 definition, a package can represent a hierarchy of registered objects, where non-terminal  
115 nodes of the hierarchy are other packages and terminal nodes are package or non-package  
116 objects. A package is a terminal node in a package hierarchy if and only if the package is  
117 empty. A registered object may be pointed to by several different packages. A package  
118 relationship between a registered package and some other registered object pointed to by  
119 a package element is represented by the *contains* role in an association instance.

120  
121 Since the representation of a registered object is defined to be a file, the file representing  
122 a package object is an XML document.

### 123 **5.2.1 Query**

124 A query is a message from a public user of a registry database to a registry, asking that  
125 certain information be returned. A request is sent in the form of an XML document that  
126 validates to one of the XML query DTD's defined elsewhere in this specification. The  
127 response to a query will validate to the associated XML response wrapper DTD.

### 128 **6.2.1 Change Request**

129 A request is a message sent from a Submitting Organization to a Registration Authority  
130 asking that certain additions or modifications be made to the Registry. A request is  
131 generally sent in the form of an XML document that validates to one of the request  
132 DTD's defined elsewhere in this specification. A request instance will consist of a request  
133 code to identify the type of request as well as the XML content of a specific request.  
134

135 Further details on the terminology definitions can be found from the OASIS Information  
136 Model document, and the ebXML Part 1 Repository specifications document.

137

## 138 **2.3 Relationship of Information Model**

139 The objective is to provide layers of XML classification syntax for the ebXML  
140 functionality of TPA, BP and CC, a legacy EDI data dictionary, TRP and any directly  
141 associated content such as UDDI that naturally overlay onto the classification system  
142 required by an ebXML compatible Registry system. Once such approach here is the  
143 ebXML GUIDE classification system (<http://www.xmlguide.org>).

144 Similarly an ebXML compatible registry change or query request can then be mapped  
145 into an existing classification XML structure. Such change or query requests can then be  
146 easily structured relative to the XML structure using WebDav style DASL querying  
147 mechanisms.

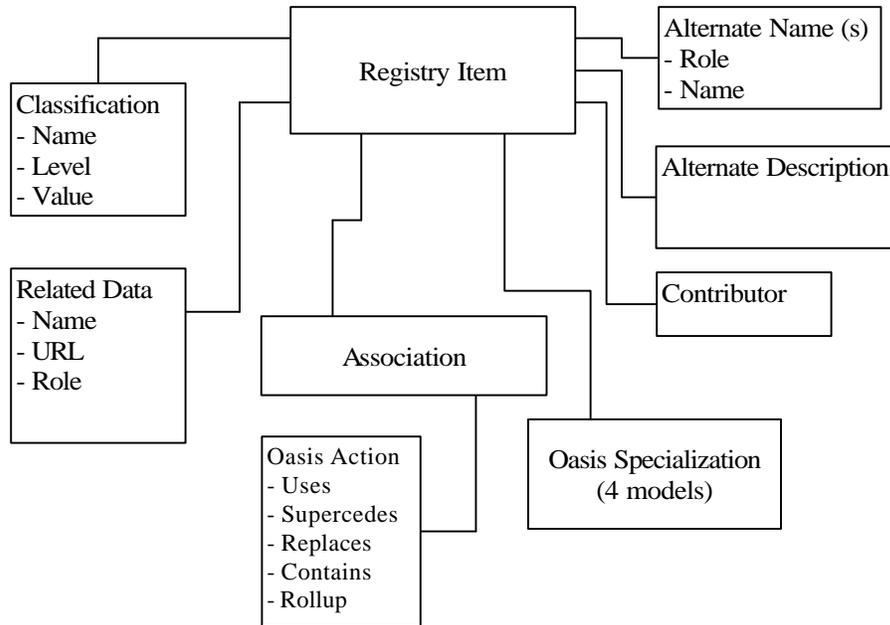

148 Further work is underway to similarly provide a bridge to an ISO11179 compatible  
149 repository at the level of the element definition layer.

150 The following figure illustrates the Registry classification model expressed as an OASIS  
151 information model. For ebXML the classification syntax noted above: TPA, TRP,  
152 BP/CC/EDI (GUIDE), and UDDI each constrain the content information model to  
153 discrete sets.

154 The difference is therefore that the OASIS design is a generalized information model,  
155 while the ebXML is designed for business transactional information use and is therefore  
156 optimized to provide those interactions.

157 Also ebXML Registry/Repository has extensions and transformation support that OASIS  
158 registry does not provide.

159 Figure 3. OASIS Registry Information Model

160

161 For more extended information on the OASIS registry specifications please see  
162 <http://www.xml.org> and associated content.

163

## 164 2.4 Attribute Types

165 Attribute values in the information model will be one of the following types:

166

- 167 • Entity References
- 168 • Base Types

169

170 Some attribute values will be references to entity instances and some will be primitive  
171 types that can be represented as character strings, numbers, dates, or dates and times.

172 Identified entity references include one of the following types:

173

174 REGISTRY\_ITEM  
175 ORGANIZATION  
176 CONTACT  
177 SUBMISSION

178

179 To this list we add the Enumeration Entities defined below.

180  
181  
182  
183  
184  
185  
186  
187  
188  
189  
190  
191  
192  
193  
194  
195  
196  
197  
198  
199  
200  
201  
202  
203  
204  
205  
206  
207  
208  
209  
210  
211  
212  
213  
214  
215  
216  
217  
218  
219  
220  
221  
222  
223

The following definitions identify the base types that will be used in this specification.

CodeText (valid XML tag name or reference URI) -- a character string consisting entirely of visible characters from an implied character set. The presence of non-visible characters, even blank spaces, is an error. In XML environments, CodeText may not contain XML characters with special meaning. These include the ampersand (&), etc.

ShortDescription -- a character string consisting of visible characters from an implied character set, together with optional use of blank spaces. Any other non-visible characters are ignored during processing, and other non-visible characters are stripped out before acceptance as a value of an attribute having this datatype.

Date -- a value that represents a calendar date, constrained by the natural rules for dates using the Gregorian calendar. A Registry will be able to respond to queries involving minimal date arithmetic, e.g. finding all instances of an entity having dates for a given attribute that fall within a given range, or finding all instances having dates in the past 30 days, or finding all registry items whose registration is scheduled to expire in the next 3 months, etc. More advanced date arithmetic or date manipulation is at the discretion of the Registry.

Date Literal -- a character string value that identifies a specific date. A date literal string is of the form YYYY-MM-DD where YYYY is an integer literal for the year, MM is an integer literal for the month of the year, and DD is an integer literal for the day of the month. Whenever a date value is presented to a user, or requested from a user, the date value is presented or transmitted as the equivalent date literal.

Datetime -- a value that represents a calendar date and a time within that date, with time precision to the minute, or finer. Unless otherwise indicated time is Universal Coordinated Time based on a 24-hour clock. A Registry has the capability to convert a Datetime type to a Date type, with the expected loss of precision. Any other datetime arithmetic or datetime manipulation is at the discretion of the Registry.

Datetime Literal -- a character string value that identifies a specific datetime. A datetime literal string is of the form YYYY-MM-DD HH:MM:SS where YYYY is an integer literal for the year, MM is an integer literal for the month of the year, DD is an integer literal for the day of the month, HH is an integer literal for the hour (assuming 24-hour clock), MM is an integer literal for the minute within the hour, and SS is an integer literal for the second within the minute. Whenever a datetime value is presented to a user, or requested from a user, the datetime value is presented or transmitted as the equivalent datetime literal.

SmallInt -- A non-negative integer with value less than 2\*\*16.

224 URNref -- a character string that conforms to the format of a Uniform Resource Name  
225 (URN) as specified by IETF RFC 1241. The length of a URNref string is less than or  
226 equal to 150 characters.  
227 (See <http://www.ietf.cnri.reston.va.us/rfc/rfc2141.txt?number=2141>)  
228  
229 URLref -- a character string that conforms to the format of a Uniform Resource Locator  
230 (URL) as specified by W3C. The length of a URLref string is less than or equal to 150  
231 characters.  
232 (See [http://www.w3.org/Addressing/URL/5\\_BNF.html](http://www.w3.org/Addressing/URL/5_BNF.html))  
233  
234 FTPref -- a character string that conforms to the format of a File Transfer Protocol (FTP)  
235 Uniform Resource Locator (URL) as specified by W3C. The default user name is  
236 "anonymous". The length of an FTPref string is less than or equal to 150 characters.  
237 (See [http://www.w3.org/Addressing/URL/5\\_BNF.html](http://www.w3.org/Addressing/URL/5_BNF.html))  
238  
239 FILEref -- a character string that is a URLref or an FTPref.  
240  
241 MIMEtype -- a character string that identifies a MIME type, as listed in the official list of  
242 all MIME media-types assigned by the IANA (Internet Assigned Number Authority). The  
243 length of a MIMEtype string is less than or equal to 150 characters.  
244 (See <ftp://ftp.isi.edu/in-notes/iana/assignments/media-types/media-types>)  
245  
246 LanguageId -- a character string that identifies a human language and a country where  
247 that language has evolved. In general, it is of the form "xx-CC", where xx is a two  
248 character code (lowercase) for a human language and CC is a two character country code.  
249 Legal strings are specified by Language Identifier, definitions [33] through [38] in W3C  
250 XML 1.0. (<http://www.w3.org/TR/REC-xml#sec-lang-tag>).  
251  
252 CharEncoding -- a character string that identifies the encoding of a character set. It is  
253 specified by the encoding name (EncName) of an Encoding Declaration, definition [81]  
254 in W3C XML 1.0.  
255 (<http://www.w3.org/TR/REC-xml#charencoding>).  
256

## 256 2.5 Enumeration Entities

257 Many of the attributes declared to be of type CodeText will have an additional constraint  
258 that the CodeText value match a specific value from a pre-defined list of values. The  
259 Registry information model represents such lists as entities with a fixed number of entity  
260 instances. We define such entities to be enumeration entities.

### 261 3.5.1 DefinitionSource

SourceCode	SourceName	Description
EbXML		Author of the ebXML Registry/Repository specification.
IEEE_LOM	IEEE Learning Technology - Learning Object Model	Author of the IEEE LOM Registry specification.
IMS		Author of the IMS Registry specification.
OASIS	Organization for the Advancement of Structured Information Standards	Author of the OASIS Registry/Repository specification.

262

### 263 4.5.1 PrimaryClassification

Source	Code	Name	Description
ebXML	defn	Definition	An XML definition document.
ebXML	inst	Instance	An XML instance document.
ebXML	pkg	Package	A package of registered items.
ebXML	other	Other (mimetype)	Binary content, must be related to a registered item.

264

### 265 5.5.1 SecondaryClassification

266 Items within definition and instance may be of related XML types such as XSL, xhtml  
267 and so forth. The default is XML, but MIMETYPE as an attribute may be used to qualify  
268 the exact content. Only content labelled by an applicable MIMETYPE will be accepted.  
269 An ebXML registry may choose to limit or validate MIMETYPE content, as it requires.

### 270 2.5.1 Submission Semantic Rules

- 271 1. The RegistryItem entity represents the set of all registered objects in the Registry.  
272 Each instance identifies a single registered object. A registry item instance holds only

273 some of the metadata for a registered object; other metadata is held by other entities  
274 in the Registry.  
275

- 276 2. Each registry item instance is assigned a unique identifier by the Registration  
277 Authority (RA). This implicit value is said to be of type REGISTRY\_ITEM. It is used  
278 to represent relationships of this instance with other information in the Registry.  
279
- 280 3. The AssignedURN name is created and assigned by the RA. It is created to be unique  
281 within a conforming Registry/Repository implementation. When a Submitting  
282 Organization (SO) makes a submission to the Registry, it provides a local reference  
283 name of type CodeText. If possible, the RA uses that name to construct the  
284 AssignedURN.  
285
- 286 4. The CommonName is provided by the SO.  
287
- 288 5. The Version is provided by the SO. It can have an arbitrary format and is used only to  
289 help distinguish one registry item from another having the same common name. The  
290 AssignedURN will be different for different versions.  
291
- 292 6. The ObjectLocation is a URL that identifies the location of the registered object. If  
293 the RA is also a repository for the item, then the RA will download the item, store it  
294 in the Repository, and create an http-based locator as a value for ObjectLocation. If  
295 the Registry is not also a Repository, then the ObjectLocation is provided by the SO  
296 and the RA has no further responsibility. The SO may also qualify the content with an  
297 AccessChannel. The ObjectLocation URL may need to be supplemented with  
298 channel and password information before the file containing the object can be  
299 retrieved. An ebXML Registry may then distinguish access to information within  
300 itself by utilizing AccessChannel rights, and assigning users to particular access  
301 channels.  
302
- 303 7. The DefnSource takes its value from the DefinitionSource enumeration entity that  
304 identifies a collection of accredited Registry/Repository development organizations.  
305 If the Registry claims conformance to the ebXML Registry/Repository, then the  
306 DefnSource is ebXML.  
307
- 308 8. The PrimaryClass is provided by the SO and takes its value from the  
309 PrimaryClassification enumeration entity. If the DefnSource is ebXML, then  
310 PrimaryClass identifies an element of the set {Definition, Instance, Package, Other}.  
311
- 312 a) The SecondaryClassification is provided by the SO and takes its value from the  
313 enumeration entity and must be a valid MIMETYPE.  
314

315 The RelatedType is provided by the SO and takes its value from the RelatedDataType  
316 enumeration entity.  
317  
318

- 319 9. The RegStatus is provided by the RA with its value taken from the RegistrationStatus  
320 enumeration entity. For ebXML registrations, that entity includes the values  
321 {Baseline, Submitted, Registered, Superseded, Replaced, Withdrawn, Expired}. The  
322 StatusChg attribute is the datetime that the RA last approved a change for RegStatus.  
323
- 324 10. The Stability attribute is provided by the SO with its value taken from the Stability  
325 enumeration entity. For ebXML registrations, that entity includes the values {Static,  
326 Dynamic, Compatible}.  
327
- 328 11. The ExpiryDate is assigned by the RA upon suggestion from the SO. Some RA's may  
329 follow very definite procedures for the length of time an object can remain registered  
330 before an affirmation or withdrawal action is required. If the Expiration date passes  
331 without an SO action, then the RA initiates an expiration action.  
332
- 333 12. The Description is provided by the SO.  
334
- 335 13. The SubmittingOrg identifies the organization submitting the registered object. It  
336 points to a unique instance of the ORGANIZATION entity. On presentation of this  
337 information, the RA substitutes the CommonName of the organization. The SO must  
338 be known to the RA before it can make submissions to the Registry/Repository, and  
339 they each know of a unique URN for the other. The process for becoming known is  
340 not part of this specification.  
341
- 342 14. The ResponsibleOrg identifies the organization responsible for the formal  
343 specification of the registered object. It points to a unique instance of the  
344 ORGANIZATION entity. The RO may be a formal accredited standards development  
345 organization or it may be the SO. On presentation of this information, the RA  
346 substitutes the CommonName of the organization.  
347
- 348 15. The PublicComment may be suggested by the SO, but it is supplied by the RA. In  
349 most cases the comment will explain some administrative process that cannot be  
350 clearly determined from the standardized information. For example, this comment  
351 may explain how long the metadata for a replaced or withdrawn object remains  
352 available, or how long an expired object remains available before it is deleted.  
353

353

354 **6.5.1 AssociationType**

Source	Code	Name	Description
ebXML	contains	Contains	Given item is a package that contains the associated item.
ebXML	related	Related	Given item is related to associated item and provides supplemental information for the associated item.
ebXML	supersedes	Supersedes	Given item supersedes associated item.
ebXML	uses	Uses	Given item uses associated item.

355

356 **7.5.1 ContactAvailability**

Source	Code	Name	Description
ebXML	Priv	Private	Contact available only to SO and RA.
ebXML	Prot	Protected	Contact available only to RA's.
ebXML	Pub	Public	Contact available to all users of registry.

357

357 **2.7.1 Structure**

<b>Attribute Name</b>	<b>Attribute Type</b>	<b>Presence</b>
AssignedURN	URNref	Mandatory
CommonName	ShortName	Mandatory
Version	CodeText	
ObjectLocation	FILEref	
DefnSource	CodeText	Mandatory
PrimaryClass	CodeText	Mandatory
SubClass	CodeText	
RelatedType	CodeText	
MimeType	MIMEtype	Mandatory
RegStatus	CodeText	Mandatory
StatusChg	Datetime	Mandatory
Stability	CodeText	Mandatory
PayStatus	CodeText	Mandatory
ExpiryDate	Date	Mandatory
Description	DescriptionText	Mandatory
SubmittingOrg	ORGANIZATION	Mandatory
ResponsibleOrg	ORGANIZATION	Mandatory
PublicComments	CommentText	

358 **2.7.2 Semantic Rules**

- 359 1. The RelatedData entity represents the set of non-registered objects that are related to  
360 registered objects. Each instance is a pairwise relationship between a single registered  
361 item and a single related data item. A registered item may map to many related data  
362 items.
- 363
- 364 2. Each instance of RelatedData depends upon a RegistryItem instance. This  
365 dependency is represented by an implicit value, RAitemId, of type  
366 REGISTRY\_ITEM.
- 367
- 368 3. The DataName attribute is provided by the SO. It is intended that this be the link  
369 name for the DataLocation if related data items are presented visually to a user.
- 370
- 371 4. The DataLocation is provided by the SO. This link is not under the control of the RA  
372 and it may point anywhere. The RA is under no obligation to ensure that the link is a  
373 valid one.
- 374
- 375 5. The RelatedType is provided by the SO and takes its value from the RelatedDataType  
376 enumeration entity. It may include values not defined by OASIS.

377

378 6. The MimeType is provided by the SO. It identifies the MIME type of the related data  
379 item. The RA is under no obligation to ensure that the declared MimeType type is  
380 consistent with the actual file type of the file referenced by DataLocation.

381

382 7. The Comment is provided by the SO. It may further explain the relationship between  
383 the related data instance and the registry item it is linked to.

## 384 **2.6 Default Classification Structures**

385 The ebXML Registry is pre-loaded with a set of default classification structures. These  
386 fall under two categories. The first category covers the ebXML components such as  
387 ebXML TRP, TPA, BP/CC and the Query/Response DASL mechanisms themselves.

388 The second category covers supporting and reference domains as elements that are basic  
389 primitives that underpin the TRP, TPA and BP/CC definitions themselves. From these  
390 basic building blocks the ebXML Registry can then accept further business domain  
391 definitions and content.

392

### 393 3. Registry Interfacing Models

394

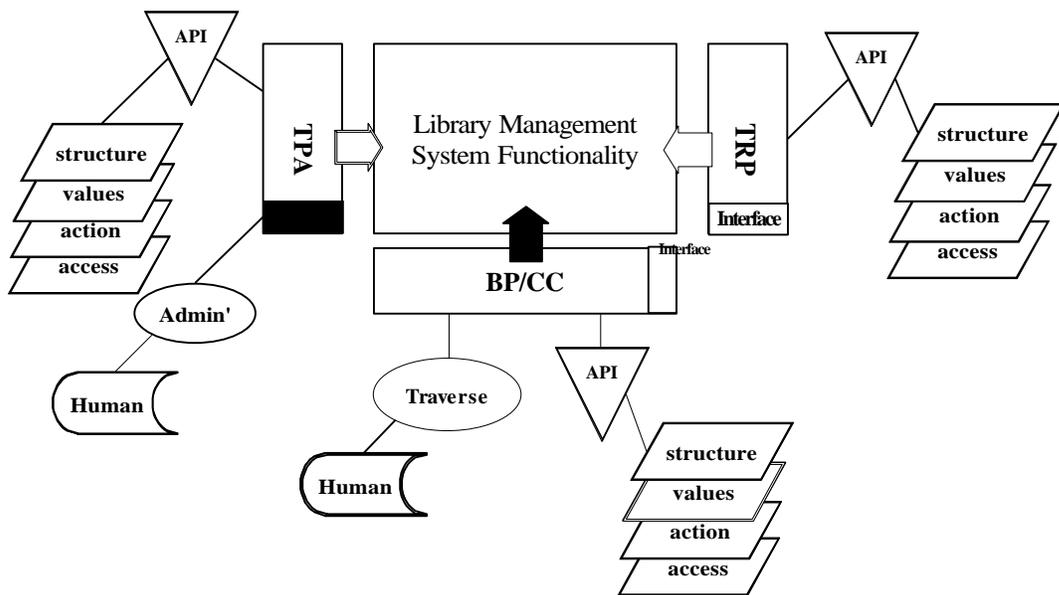

#### 395 3.1 Relation to IETF WebDav DASL work

396 Generally speaking the ebXML approach is to follow the DASL approach and provide a  
397 focused subset of a business functional feature set based on those technology neutral  
398 technical specifications (see <http://www.webdav.org> for more details). The WebDav  
399 DASL approach provides an ideal widely supported lightweight XML based interaction  
400 model.

#### 401 3.2 Interfacing Models

402 The ebXML Technical Architecture specifications detail the actual registry/repository  
403 interfacing required for each of the components of ebXML. The figure shown here  
404 illustrates these as a set of interface services to be provided. This approach allows us to  
405 define discrete interface XML structures to implement these with.

406 Figure 4. The ebXML Registry Interfaces

407

408 Shown are three interface components to the major ebXML modules of TRP, TPA and  
409 BP/CC. The role and actors (see ebXML Registry/Repository Specifications Part 1)  
410 determine the types of interactions supported by these interfaces. Therefore TRP does

411 not warrant a human interface capability since only machine-to-machine interactions are  
412 required with the Registry.

413 The library management system functionality essentially treats the internal mechanisms  
414 within the ebXML Registry implementation as a 'blackbox' that supports the  
415 requirements as laid out in both the overall ebXML Requirements document, the  
416 Registry/Repository Part 1 and the Registrar, DocumentManager and TPAManager noted  
417 elsewhere in this document. This approach allows any such capable existing document  
418 management or library system to be exposed as an ebXML Registry using the appropriate  
419 WebDav DASL interfacing bindings.

420 Each of the interfaces is now described functionally and then in the following section  
421 actually interchange XML structure specifications are shown. The common theme is that  
422 any registry interface will consist of the components, Access, Action, Structure and  
423 Values. These correspond to the similar DASL approach of technology neutral bindings.

424 The definition of each of these is:

- 425 1. Access - The profile that describes the access allowed, includes an optional channel  
426 through which information is accessed, and an associated user account and optional  
427 password. The user account will have an associated ebXML TPA profile.
- 428 2. Action – The particular action to be performed, either a Query, or a Change Request  
429 and then an optional post-processing action and optional error action.
- 430 3. Structure – the associated XML structure of both the request format and also the  
431 response format. These will be associated using either a URL or a namespace.
- 432 4. Values – the actual content values in either the request, or the response XML payload  
433 details.

### 434 **3.2.1 The TRP Interface Model**

435 The TRP interface provides a machine level Application Programming Interface (API)  
436 using WebDav DASL based interactions. The TRP interface is primarily concerned with  
437 verifying transport related content in the ebXML-messaging envelope. For this it  
438 requires to access classification structure information, semantic business information and  
439 actual content values to ensure compliance. Therefore request/response mechanisms are  
440 required for these interactions. The interaction content and functionality themselves are  
441 more fully described in the ebXML TRP Specifications.

### 442 **4.2.1 The TPA Interface Model**

443 The TPA interface provides both a machine level API and a human level interface. The  
444 human level interface is required to support TPA management and administration. While  
445 API calls will underpin the actual human interface, and the actual mechanics and look  
446 and feel of the human interface are not prescribed, it is important to state in the  
447 specifications that a human interface is provided. This is to ensure that authentication  
448 and verification of critical trading partner information is possible locally for the registry

449 administrator, and other than through a remote API interface. The specific human  
450 interface functionality that is required is:

- 451 1. The ability to query on and review an individual TPA entry details.
- 452 2. The ability to update and change an individual TPA entry details.
- 453 3. The ability to setup access profiles and then to assign these to TPA entries.

454 Meanwhile the API machine-to-machine interfacing provides trading partner information  
455 to compliment the TRP API by providing specific verification information and also to  
456 provide search capabilities for Business Process related querying. Therefore the TPA  
457 API interface may be used to discover capable trading partners within an industry or  
458 business process domain. Again, the TRP messaging specifications are sufficiently clear  
459 on the requirements to access TPA content and at that level of access require strictly  
460 query/response interchanges with optional access logging to implement.

### 461 **5.2.1 The BP/CC (ebXML GUIDE) Interface Model**

462 The BP/CC interface provides both a machine level API and a human traversal discovery  
463 interface. This human interface is intended primarily to be used by business analyst staff  
464 researching content and business processes within the registry. Such human interface  
465 interactions are intended to use a topic map style presentation of the related information  
466 within the Registry organized according to the business process classification system  
467 inherent in the Registry. The ebXML GUIDE specifications provide the classification  
468 layer content to drive this functionality and the ebXML BP and CC specifications provide  
469 the specialized content structures within the classification layer. This functionality is also  
470 a discrete focused business tool that allows industry domains to publish their business  
471 processes either generically, or particular to either groups of trading partners or  
472 individual businesses within the industry. While API calls will underpin the actual  
473 human interface, and the actual mechanics and look and feel of the human interface are  
474 not prescribed, it is important to state in the specifications that a human interface is  
475 provided. Each industry implementation may differ in the style of information  
476 presentation and scope made available and this specification is not attempting to dictate  
477 those aspects. Instead a list is presented here of human functionality that can be enabled.

- 478 1. Tree based topic map traversable structure that provides a review of business domain,  
479 and the industry partners and the business processes supported by the registry.
- 480 2. Ability to query on a specific classification details within an industry and return a list  
481 of applicable element definitions for review.
- 482 3. Ability to query on an item by unique reference identifier and return that content item  
483 for display and review.
- 484 4. The ability to submit changes to the content details within the registry.

485

486 The machine API calls that underpin the human interface then provide the same  
487 functionality in machine-to-machine interfacing with the BP/CC content within the

488 Registry. By specifying a discrete set of ebXML GUIDE classification structures this  
489 reduces the need for ebXML based business applications to perform complex discovery  
490 interactions with an ebXML Registry to determine the actual semantics of information  
491 content. This both speeds access and makes for more consistently interoperable  
492 interchanges.

### 493 **6.2.1 Alignment with TRP Interface and Security Model**

494 Reviewing the DASL approach and the MIME based approach TRP approach there are  
495 significant similarities in the formatting and structure of the interchanges. We do not  
496 anticipate that the differences where they exist between the two systems will present  
497 particular implementation challenges, particularly as WebDav is now a widely supported  
498 open cross-platform specification.

499 The TRP messaging model already has an envelope structure that contains specific  
500 information regarding the trading partner and authentication and verification information.  
501 However, these same mechanisms are not always applicable to adopting wholesale for  
502 the Registry access, as the business functional needs are different. We also face a very  
503 real 'Catch22' situation where the information in the TRP header requires access to the  
504 Registry to access the TPA within the Registry. The solution is to link the Registry  
505 WebDav DASL accessing to the same content as the TRP exchange uses for TPA  
506 verification within the Registry through a lightweight DASL query mechanism that still  
507 provides sufficient security and authentication measures. Such information inside the  
508 TRP envelope can then be optional encrypted using the recipient's public encryption key.  
509 The TRP services can then issue DASL requests based off the information in the TRP  
510 envelope header alone and this then ensures consistency.

511 The WebDav DASL system also has its own error response handling system, so this  
512 removes the need for ebXML Registry/Repository interfaces to define these mechanisms  
513 as they are provided in the interchange.

514

515

### 515 3.3 Examples of Registry Interfacing

516 The WebDav DASL approach provides an ideal widely supported lightweight XML  
517 based interaction model.

518 Further more the DASL system provides an extensible interface specification, so ebXML  
519 compatible query and response structures can be registered and then utilized within a  
520 DASL XML wrapper. For more information on DASL see <http://www.webdav.org> ).

#### 521 Example 1 ebXML Registry DASL query structure

522 This example illustrates a simple query to return a structure content item from the  
523 registry. The request below is an implicit XML structure based system that is keyed off  
524 the base ebXML classification structures within the ebXML Registry. Since an ebXML  
525 Registry is not an arbitrary collection of unordered information, but instead is a focused  
526 set of related content the request can utilize basic primitive aspects of the ebXML  
527 Registry to enable the request interface system.

```
528 SEARCH / HTTP/1.1
529 Content-Type: text/xml
530 Connection: Close
531 Content-Length: 632
532
533 <?xml version="1.0" ?>
534 <!-- ebXML Registry Structure Request V0.1 -->
535 <D:searchrequest xmlns:D="DAV:" xmlns:eb="ebXML:">
536   <eb:request>
537     <eb:access>
538       <eb:channel>anonymous</eb:channel>
539       <eb:auth user="klaus" password="76778jjk" />
540     </eb:access>
541     <eb:input>
542       <eb:match>
543         <eb:item name="domain" value="GCI"/>
544         <eb:item name="qic" value="GCI07090"/>
545       </eb:match>
546       <eb:select>
547         <eb:version>00</eb:version>
548         <eb:content>structure</eb:content>
549         <eb:parent>root</eb:parent>
550       </eb:select>
551       <eb:operation>
552         <eb:pageSize>10</eb:pageSize>
553         <eb:hitCount>1</eb:hitCount>
554       </eb:operation>
555     </eb:input>
556     <eb:output type="content" />
557   </eb:request>
558 </D:searchrequest>
```

559 Reviewing the request structure above the <eb:match> block contains references to  
560 domain and qic items that are part of the ebXML GUIDE classification scheme so  
561 therefore these are known structural elements that can be searched on. In fact any  
562 element within the registry can be searched on in context using this technique. DASL  
563 also provides the means to specify selection operatives such as <or> and <and> to adjust  
564 the search behaviour. By default a <eb:match> block is an implicit logical and of all  
565 items specified. This behaviour will accommodate most common requests to the  
566 Registry.

567 In the <eb:select> block a request for version '00' will return the latest version available,  
568 and the content and parent elements indicate that we require the complete structure of the  
569 matching XML content. The <eb:operation> block controls the behaviour of the search  
570 process itself. Again DASL provides these mechanisms to control the operation of the  
571 search system.

572 Then the <eb:output> block controls how the output is returned to the invoking system.  
573 The "content" parameter causes the default behaviour of returning the physical content,  
574 the other option is to return a URL pointer structure that can be used to reference the  
575 physical content itself.

576

576 **Example 2 ebXML Registry DASL response structure**

577 The corresponding response mechanism is now shown for the request query in Example 1  
578 above.

```
579 HTTP/1.1 207 Multi-Status
580 Content-Type: text/xml
581 Content-Length: 2032
582
583 <?xml version="1.0" ?>
584   <D:multistatus xmlns:D="DAV:" xmlns:eb="ebXML"
585   xmlns:R="http://www.ebxml.org/dasl-resp-schema">
586     <D:response>
587       <D:href />
588       <D:propstat>
589         <D:prop>
590           <R:author>Ravi Kraft</R:author>
591           <R:title>Catalogue Manifest</R:title>
592           <R:synopsis>Vendor Catalogue Inventory Details</R:synopsis>
593           <R:last-modified>1999-12-25T112222PST</R:last-modified>
594           <R:size unit="kilobytes">3</R:size>
595           <R:extra-info />
596           <R:external-doc-id />
597           <R:doc-id>11227726625</R:doc-id>
598         </D:prop>
599       </D:propstat>
600     <eb:structure>
601     <![CDATA[
602     <!-- Main definition of CatXML content schema V 1.1 -->
603     <!ELEMENT Input (Schema , Content )>
604     <!ELEMENT Schema (#PCDATA )>
605     <!ELEMENT Content (Vendor? , Supplier? , StockInfo? , ShipInfo? , Item
606     )>
607     <!-- Establish link to qic reference location -->
608     <!ATTLIST Content
609       qicref CDATA #FIXED "http://www.catxml.org/qic/datatypes.xml" >
610
611     <!ELEMENT Vendor (CompanyID , Name? , Address? , Contact? )>
612     <!ATTLIST Vendor
613       vendorID ID #IMPLIED >
614     <!ELEMENT CompanyID (#PCDATA )>
615     <!ATTLIST CompanyID
616       context (Vendor|Supplier|Manufacturer|Other) 'Vendor'
617       idType (DUNS|Local|USDoD|EIN|TaxID|Other) 'DUNS' >
618     <!ELEMENT Name (#PCDATA)>
619     <!ENTITY % addressInfo SYSTEM "CatXML-address-V1.dtd" >
620     <!ENTITY % contactInfo SYSTEM "CatXML-contact-V1.dtd" >
621     <!ENTITY % shippingInfo SYSTEM "CatXML-shipping-V1.dtd" >
622     <!ENTITY % usgovDoDInfo SYSTEM "CatXML-usgovDoD-V1.dtd" >
623     <!ENTITY % stockInfo SYSTEM "CatXML-warehouse-V1.dtd" >
624
625     %addressInfo;
626     %contactInfo;
```

```
627 %shippingInfo;  
628 %usgovDoDInfo;  
629 %stockInfo;  
630 ]]>  
631 </eb:structure>  
632 </D:response>  
633 </D:multistatus>
```

634 The next example shows a return of a link reference to repository content rather than the  
635 physical content itself.

636

### 637 **Example 3 ebXML Registry DASL response structure**

638 The corresponding response mechanism is now shown for the request query in Example 1  
639 above where the <eb:output> block request is changed to specify a URL instead of the  
640 content itself.

```
641 HTTP/1.1 207 Multi-Status  
642 Content-Type: text/xml  
643 Content-Length: 763  
644  
645 <?xml version="1.0" ?>  
646 <D:multistatus xmlns:D="DAV:" xmlns:eb="ebXML"  
647 xmlns:R="http://www.ebxml.org/dasl-resp-schema">  
648 <D:response>  
649 <D:href>http://www.GCI.org/ebXML/catalogue.xml</D:href>  
650 <D:propstat>  
651 <D:prop>  
652 <R:author>Duane Nickull</R:author>  
653 <R:title>Catalogue Manifest</R:title>  
654 <R:synopsis>Vendor Catalogue Inventory Details</R:synopsis>  
655 <R:last-modified>1999-12-25T112222PST</R:last-modified>  
656 <R:size unit="kilobytes">12</R:size>  
657 <R:extra-info />  
658 <R:external-doc-id />  
659 <R:doc-id>11227726625</R:doc-id>  
660 </D:prop>  
661 </D:propstat>  
662 </D:response>  
663 </D:multistatus>
```

664 The next example illustrates a change request interchange.

665

665 **Example 4 ebXML Registry DASL change request structure**

666 TBD

667

## 667 **3.4 The ebXML RegRep linking**

668 The linking mechanism used in ebXML RegRep is based on either http URL links or  
669 XML namespaces. The reserved word eb namespace declared in the root tag of the XML  
670 transaction instance establishes the reference to the next ebXML RegRep content layer as  
671 needed. Therefore a XML transaction will use the eb namespace to reference the  
672 structure schema that defines the structural rules, and the eb structure will in turn use its  
673 own *element* namespace to locate the default element definitions associated with the  
674 structure. The element definitions can also optionally access the *datatypes* namespace to  
675 locate datatyping information. This provides an extensible datatype model.

676 However, fragments that are themselves included, may not have further *include*  
677 references within them, thus ensuring that only one level of nesting is provided.  
678 Furthermore, permitting only the single ebXML namespace with a single control  
679 structure ensures that the true structure of transactions is available and exposed. This  
680 contrasts with other early schema implementations that used in-line namespace  
681 definitions to retrieve multiple structure schemas, thus creating a system where the true  
682 transaction structure could not be determined. The ebXML RegRep avoids this by only  
683 allowing the single guide namespace for including the structure linkage.

684 This linkage mechanism is designed to be simple and business functional and to avoid  
685 any complex constructs that make registry implementation and behaviour complex or  
686 uncertain. This necessarily restricts the complex use of cascading links, and in  
687 particular linking can only be nested one layer deep, and all recursive references are  
688 explicitly not provided.

## 689 **3.5 Type systems**

690 The ebXML RegRep element definitions use basic business datatypes. All of these are  
691 supported by the current W3C datatyping proposal, however the W3C has extended  
692 complex behaviours in their datatyping. Any item that does not have a datatype  
693 explicitly assigned is treated as a simple string by default.

## 694 **3.6 Relationship of and use of Bizcodes**

695 The Qualified Indicator Code (QIC) is tied into the Bizcode mechanism that provides the  
696 linkage between ebXML classification structures and the associated element definitions  
697 and is designed to be a neutral reference code. Use of neutral reference codes is already  
698 an established practice within dictionaries of industry element definitions. Therefore  
699 many industries already have codes that they can use as QIC references.

700 The preferred Bizcode QIC structure is a three-letter code, followed by a five-digit  
701 number, where the three-letter code denotes the industry or group assigning the codes,  
702 and the five-digit number is a sequentially assigned value. It is anticipated that as part of  
703 the ebXML repository technical specifications there will also be guidelines established

704 for managing globally unique names under which Bizcode QIC references can be  
705 classified.

706 Currently the barcodes used for product labelling are managed in a similar fashion by  
707 having formally registered barcodes alongside locally defined barcodes. With Bizcode  
708 QIC labels, since they are tightly coupled to an ebXML classification structure and also  
709 stored within an ebXML element repository this already provides excellent separation to  
710 avoid conflicts on QIC values assigned within an industry. Also, unlike barcodes where  
711 there are many tens of millions already assigned, Bizcodes required a much more limited  
712 number since they are reusable across many products. An example is the food industry  
713 where there are over seven million barcodes in use, but less than ten thousand unique  
714 element definitions (product attributes) are being used to describe all those products.

715 The current ebXML GUIDE element classification structure is designed to be compatible  
716 with ISO11179 based reference registries. The role of ISO11179 registries is to  
717 harmonize information classification within a corporation or large government agency for  
718 human analytical and business system design purposes. The role of ebXML repositories  
719 extends beyond that to include XML based machine-to-machine information interchanges  
720 that reference XML repositories via an XML based API and interface specifications.

721 Therefore ebXML GUIDE classification can be used in tandem with ISO11179, where  
722 the ISO registry manages the content that the ebXML system exposes to ebXML aware  
723 systems.

724

724

## 725 **4. Tutorial and Use Case**

726 This section presents a short example by the way of an illustration of how to work  
727 with and prepare an ebXML RegRep transaction. This section should reference the  
728 Tokyo POC implementation documentation.

## 729 **5. Addendum**

### 730 **A 1. References**

731 W3C Working Draft "[XML Schema Part 1: Structures](#)". This is work in progress.

732 W3C Working Draft "[XML Schema Part 2: Datatypes](#)". This is work in progress.

#### 733 **A 1.1 Notes on URI, XML namespaces & schema locations**

734 Namespace use to be defined with regard to the W3C namespace recommendation.

#### 735 **A 1.2 Relative URIs**

736 Throughout this document you see fully qualified URIs used as references. The use of a  
737 fully qualified URI is simply to illustrate the referencing concepts.

738
